## Ergodicity Theorem

If  $P$  is irreducible and aperiodic, then there is a unique stationary distribution  $\pi$  such that

$$\forall x, \lim_{t \rightarrow \infty} P^t(x, \cdot) = \pi$$

**Thoughts** This theorem can be proved by using coupling, which is shown in another note by Boyu Tian. Now we introduce an extension of this theorem in which we will prove the long-term average probability distribution  $a^t(x, \cdot) = \frac{1}{t}(P^0(x, \cdot) + P^1(x, \cdot) + \cdots + P^{t-1}(x, \cdot))$  will also converge to  $\pi$ .

## Extension

Let  $a^t(x, \cdot)$  be the long term average probability distribution,

$$a^t(x, \cdot) = \frac{1}{t}(P^0(x, \cdot) + P^1(x, \cdot) + \cdots + P^{t-1}(x, \cdot))$$

For an irreducible and aperiodic Markov chain, there is a unique stationary distribution  $\pi$  subject to

$$\forall x, \lim_{t \rightarrow \infty} a^t(x, \cdot) = \pi$$

### Proof 1:

**Lemma** Let  $P$  be the transition probability matrix for a connected Markov chain. The  $n \times (n + 1)$  matrix  $A = [P - I, 1]$  obtained by augmenting the matrix  $P - I$  with an additional column of ones has rank  $n$ .

**Proof:** We prove the lemma by contradiction. We assume that the rank of  $rank(A) < n$ . Then the subspace of solutions to  $Ax = 0$  is at least  $n + 1 - (n - 1) \geq 2$  dimensions. Each row in  $P$  sums to one, so each row in  $P - I$  sums to 0. Thus  $x_0 = (\mathbf{1}, 0)$  whose entries are all 1 but the last one is 0, is a solution to  $Ax = 0$ . Assume there was a second solution  $(x, \alpha)$  different with  $(\mathbf{1}, 0)$ . Then  $(P - I)x + \alpha \mathbf{1} = 0$  and  $\forall i, x_i = \sum_j p_{ij}x_j + \alpha$ . Let  $S_{max}$  be the set of  $i = \operatorname{argmax}_i x_i$ . As  $x$  differ from  $\mathbf{1}$ ,  $\bar{S} \neq \emptyset$ . Irreducible implies that for some  $k \in S$ ,  $x_k$  is adjacent to some xl of lower value. Thus,  $x_k > \sum_j p_{kj}x_j \Rightarrow \alpha > 0$ .

On the other hand, for the set  $S_{min}$  of  $i = \operatorname{argmin}_i x_i$ , we can prove that  $\alpha < 0$ . A contradiction!

**Proof for theorem:** Similar to the lemma above, let  $A = [P - I, \mathbf{1}]$ . And let  $B = A(:, 2 : \text{end})$  (a notation from matlab, which means that construct a matrix consisting the second column to the last of A). As the sum of each row of  $P - I$  is 0, the first  $n$  column must be relevant. According to the lemma,  $rank(A) = n$ , and the first  $n$  column of A is relevant, so  $rank(B) = n$ .

Consider,

$$\begin{aligned} a^t(x, \cdot)P - a^t(x, \cdot) &= \frac{1}{t}(P^0(x, \cdot)P + P^1(x, \cdot)P + \cdots + P^{t-1}(x, \cdot)P) \\ &\quad - \frac{1}{t}(P^0(x, \cdot) + P^1(x, \cdot) + \cdots + P^{t-1}(x, \cdot)) \\ &= \frac{1}{t}(P^t(x, \cdot) - P^0(x, \cdot)) \end{aligned}$$

Let  $b^t(x, \cdot) = a^t(x, \cdot)P - a^t(x, \cdot)$ . We have that  $|b^t(x, \cdot)| \leq \frac{2}{t} \rightarrow 0$ , as  $t \rightarrow \infty$ . Let  $c^t(x, \cdot)$  be a vector containing all of the entries of  $b^t(x, \cdot)$  except the first entry. Therefore,

$$\begin{aligned} a^t(x, \cdot)B &= [a^t(x, \cdot)P - a^t(x, \cdot), 1](:, 2 : \text{end}) \\ &= [b^t(x, \cdot), 1](:, 2 : \text{end}) \\ &= [c^t(x, \cdot), 1] \rightarrow [\mathbf{0}, 1] \end{aligned}$$

As proved before, B is invertible. Therefore,

$$a^t(x, \cdot) \rightarrow [\mathbf{0}, 1]B^{-1}, \text{ as } t \rightarrow \infty$$

Because,  $a^t(x, \cdot)P - a^t(x, \cdot) = b^t(x, \cdot) \rightarrow 0$ , we have,

$$[\mathbf{0}, 1]B^{-1}P = [\mathbf{0}, 1]B^{-1}, \text{ i.e. } \pi = [\mathbf{0}, 1]B^{-1}$$

**Proof 2:**
